Project Description

This project is a simple beginner-level web server application developed using **Node.js** and the **Express.js** framework. The main objective of this project is to understand the basic concepts of backend development, server creation, and routing in a Node.js environment. It is designed as a first practice project for learning how web servers work and how different routes can respond with different outputs.

The application creates a basic Express server that runs on port **3000**. Using Express routing, different endpoints are defined to return different responses when accessed through a browser. For example, when the root route (/) is accessed, the server returns a simple text response. Additional routes such as /name and /id return specific information. This demonstrates how Express can handle multiple routes and send responses to clients based on the requested URL.

The project structure follows the standard Node.js application format. It includes important files such as server.js (or app.js) which contains the server code, package.json which manages project dependencies, and package-lock.json which ensures consistent package installation. The Express package is used to simplify HTTP request handling and server setup.

This project is useful for beginners who want to start learning backend development with Node.js. It helps in understanding basic concepts such as server creation, routing, HTTP responses, and running a Node.js application through the terminal.

Overall, this project serves as a foundation for learning more advanced topics such as API development, database integration, middleware usage, and full-stack web application development.

If you want, I can also give you a **professional README format for GitHub** with sections like:

- Project Overview
- Installation
- Usage
- Project Structure
- Future Improvements

which will make your repository **look much more professional**.
